Lecture 3: Exponential Coordinate of Rigid Body Configuration

Prof. Wei Zhang

Southern University of Science and Technology, Shenzhen, China

Outline

- Exponential Coordinate of $SO(3)$
- Euler Angles and Euler-Like Parameterizations
- Exponential Coordinate of $SE(3)$

Outline

- Exponential Coordinate of $SO(3)$
- Euler Angles and Euler-Like Parameterizations
- Exponential Coordinate of $SE(3)$

Towards Exponential Coordinate of $SO(3)$

- Recall the polar coordinate system of the complex plane:
 - Every complex number $z = x + jy = \rho e^{j\phi}$
 - Cartesian coordinate $(x, y) \leftrightarrow$ polar coordinate (ρ, ϕ)
 - For some applications, polar coordinate is preferred due to its geometric meaning.

- Consider a set $M = \{(t, \sin(2n\pi t)) : t \in (0, 1), n = 1, 2, 3, \dots\}$

$$M \subseteq \mathbb{R}^2$$

$$p \in M; \quad p = (x_p, y_p)$$

- Take advantage of structure of M
coordinate of $p: (1, x_p) \leftrightarrow (x_p, \sin(\dots))$

Exponential Coordinate of $SO(3)$

- **Proposition** [Exponential Coordinate $\leftrightarrow SO(3)$]

- For any unit vector $[\hat{\omega}] \in so(3)$ and any $\theta \in \mathbb{R}$,

$$e^{[\hat{\omega}]\theta} \in SO(3)$$

- For any $R \in SO(3)$, there exists $\hat{\omega} \in \mathbb{R}^3$ with $\|\hat{\omega}\| = 1$ and $\theta \in \mathbb{R}$ such that

$$R = e^{[\hat{\omega}]\theta}$$

$$\text{exp: } [\hat{\omega}]\theta \in so(3) \quad \rightarrow \quad R \in SO(3)$$

$$\text{log: } R \in SO(3) \quad \rightarrow \quad [\hat{\omega}]\theta \in so(3)$$

- The vector $\hat{\omega}\theta$ is called the *exponential coordinate* for R
- The exponential coordinates are also called the canonical coordinates of the rotation group $SO(3)$

Rotation Matrix as Forward Exponential Map

- Exponential Map: By definition

$$e^{[\omega]\theta} = I + \theta[\omega] + \frac{\theta^2}{2!}[\omega]^2 + \frac{\theta^3}{3!}[\omega]^3 + \dots$$

- **Rodrigues' Formula:** Given any unit vector $[\hat{\omega}] \in so(3)$, we have

$$e^{[\hat{\omega}]\theta} = I + [\hat{\omega}] \sin(\theta) + [\hat{\omega}]^2 (1 - \cos(\theta))$$

Logarithm of Rotations

- If $R = I$, then $\theta = 0$ and $\hat{\omega}$ is undefined.

- If $\text{tr}(R) = -1$, then $\theta = \pi$ and set $\hat{\omega}$ equal to one of the following

$$\frac{1}{\sqrt{2(1+r_{33})}} \begin{bmatrix} r_{13} \\ r_{23} \\ 1+r_{33} \end{bmatrix}, \frac{1}{\sqrt{2(1+r_{22})}} \begin{bmatrix} r_{12} \\ 1+r_{22} \\ r_{32} \end{bmatrix}, \frac{1}{\sqrt{2(1+r_{11})}} \begin{bmatrix} 1+r_{11} \\ r_{21} \\ r_{31} \end{bmatrix}$$

- Otherwise, $\theta = \cos^{-1} \left(\frac{1}{2}(\text{tr}(R) - 1) \right) \in [0, \pi)$ and $[\hat{\omega}] = \frac{1}{2\sin(\theta)}(R - R^T)$

Outline

- Exponential Coordinate of $SO(3)$
- Euler Angles and Euler-Like Parameterizations
- Exponential Coordinate of $SE(3)$

Euler Angle Representation of Rotation

- A common method of specifying a rotation matrix is through three independent quantities called **Euler Angles**.
- Euler angle representation
 - Initially, frame $\{0\}$ coincides with frame $\{1\}$
 - Rotate $\{1\}$ about \hat{z}_0 by an angle α , then rotate about \hat{y}_a axis by β , and then rotate about the \hat{z}_b axis by γ . This yields a net orientation ${}^0R_1(\alpha, \beta, \gamma)$ parameterized by the ZYZ angles (α, β, γ)
 - ${}^0R_1(\alpha, \beta, \gamma) = R_z(\alpha)R_y(\beta)R_z(\gamma)$

Other Euler-Like Parameterizations

- Other types of Euler angle parameterization can be devised using different ordered sets of rotation axes
- Common choices include:
 - ZYX Euler angles: also called *Fick angles* or yaw, pitch and roll angles
 - YZX Euler angles (Helmholtz angles)

Outline

- Exponential Coordinate of $SO(3)$
- Euler Angles and Euler-Like Parameterizations
- Exponential Coordinate of $SE(3)$

Exponential Map of $se(3)$: From Twist to Rigid Motion

Theorem 1 [Exponential Map of $se(3)$]: For any $\mathcal{V} = (\omega, v)$ and $\theta \in \mathbb{R}$, we have $e^{[\mathcal{V}]\theta} \in SE(3)$

- Case 1 ($\omega = 0$): $e^{[\mathcal{V}]\theta} = \begin{bmatrix} I & v\theta \\ 0 & 1 \end{bmatrix}$
- Case 2 ($\omega \neq 0$): without loss of generality assume $\|\omega\| = 1$. Then

$$e^{[\mathcal{V}]\theta} = \begin{bmatrix} e^{[\omega]\theta} & G(\theta)v \\ 0 & 1 \end{bmatrix}, \text{ with } G(\theta) = I\theta + (1 - \cos(\theta))[\omega] + (\theta - \sin(\theta))[\omega]^2 \quad (1)$$

Log of $SE(3)$: from Rigid-Body Motion to Twist

Theorem 2 [Log of $SE(3)$]: Given any $T = (R, p) \in SE(3)$, one can always find twist $\mathcal{S} = (\omega, v)$ and a scalar θ such that

$$e^{[\mathcal{S}]\theta} = T = \begin{bmatrix} R & p \\ 0 & 1 \end{bmatrix}$$

Matrix Logarithm Algorithm:

- If $R = I$, then set $\omega = 0$, $v = p/\|p\|$, and $\theta = \|p\|$.
- Otherwise, use matrix logarithm on $SO(3)$ to determine ω and θ from R . Then v is calculated as $v = G^{-1}(\theta)p$, where

$$G^{-1}(\theta) = \frac{1}{\theta}I - \frac{1}{2}[\omega] + \left(\frac{1}{\theta} - \frac{1}{2}\cos\frac{\theta}{2}\right)[\omega]^2$$

Exponential Coordinates of Rigid Transformation

- To sum up, screw axis $\mathcal{S} = (\omega, v)$ can be expressed as a normalized twist; its matrix representation is

$$[\mathcal{S}] = \begin{bmatrix} [\omega] & v \\ 0 & 0 \end{bmatrix} \in se(3)$$

- A point started at $p(0)$ at time zero, travel along screw axis \mathcal{S} at unit speed for time t will end up at $\tilde{p}(t) = e^{[\mathcal{S}]t}\tilde{p}(0)$
- Given \mathcal{S} we can use Theorem 1 to compute $e^{[\mathcal{S}]t} \in SE(3)$;
- Given $T \in SE(3)$, we can use Theorem 2 to find $\mathcal{S} = (\omega, v)$ and θ such that $e^{[\mathcal{S}]\theta} = T$.
- We call $\mathcal{S}\theta$ the **Exponential Coordinate** of the homogeneous transformation $T \in SE(3)$
